MEMORANDUM

October 28, 2005

To: Martin Elvis, SDS Group Leader
From: Glenn E. Allen, SDS, for the CTI task group
Subject: Adjusting ACIS Event Data to Compensate for CTI
Revision: 4.10
URL: <http://space.mit.edu/CXC/docs/docs.html#cti>
File: `/nfs/cxc/h2/gea/sds/docs/memos/memo_cti_correction_4.10.tex`

The ACIS instrument teams at PSU and MIT have shown that a significant improvement in the energy resolution of existing ACIS event data can be obtained by compensating for some of the effects of the parallel charge-transfer inefficiency (CTI) of the front-illuminated CCDs. To achieve this improvement, charge is added to each $3 \text{ pixel} \times 3 \text{ pixel}$ event island and the charge within the event island is redistributed. The amount of charge added to each event is based on an estimate of the average amount of charge that is lost as charge packets are clocked across the charge traps on the ACIS detectors. The average amount of charge lost depends on the density of charge traps on the detector, the location of the event on the CCD, and the number of traps that have already been filled by “precursor events” in the same CCD column (i.e. on how many empty traps an event must cross to get to the read out). The tool `acis_process_events` includes the algorithm described in section 1.4, which can be used to compute the CTI-adjusted values of PHAS. These adjusted values are contained in a new column called PHAS_ADJ. The original, unadjusted values are retained in the column PHAS. Once the values of PHAS_ADJ are computed, the values of FLTGRADE, GRADE, PHA, ENERGY, and PI are computed using the column PHAS_ADJ. At the present, the calibration data is only appropriate for data obtained using some of the front-side-illuminated CCDs with frame times of about 3.2 s.

1 Changes to `acis_process_events`

1.1 Additional Parameters

1. `apply_cti,b,a`, “yes”, “no”, “yes”, “Apply CTI adjustment?”
2. `ctifile,s,h`, “CALDB”, “”, “ACIS CTI ARD file (NONE — none — CALDB — <filename>)”
3. `max_cti_iter,i,h`, 15, 1, 20, “Maximum number of iterations for the CTI adjustment of each event”
4. `cti_converge,r,h`, 0.1, 0.1, 1.0, “The convergence criterion for each CTI-adjusted pixel in adu”

When Catherine Grant tested the PSU CTI-adjustment tool, she found that the median number of iterations required to satisfy a convergence criterion of 0.1 adu is four. No event required more than ten iterations. Therefore, a default maximum of fifteen iterations should be sufficient to estimate the distribution of the charge deposited in the detector. We suggest that the maximum number of iterations be limited to

the range of 1–20. The default convergence criterion is set to 0.1 adu because this is the default value used for the PSU CTI-adjustment tool. Since the utility of using values smaller than 0.1 adu is questionable, the minimum value for the parameter `cti_converge` is 0.1 adu. A maximum value of 1 adu seems reasonable for the convergence parameter.

1.2 Additional Input

The tool `acis_process_events` must read the CTI ARD file in addition to the other files it already reads. The format of the CTI ARD file is summarized in section 2.

1.3 Additional Output

If `apply_cti = "yes,"` the output event file has the same format as the present Level 1 or 2 ACIS event files except that the file includes the additional column “PHAS_ADJ” (if specified as part of the eventdef) and the additional keywords “CTIFILE” and “CTLCORR” (= T). The new column contains the real (not integer) CTI-adjusted values of the charge distribution in the event island. The column named PHAS contains the original, unadjusted values of PHAS (i.e. the bias and overlock-subtracted values of PHAS obtained before any CTI adjustment is performed). The keyword CTIFILE contains the name of the CTI ARD file used to process the data. If `apply_cti = "no,"` no CTI adjustment is applied, the column PHAS_ADJ is not created, the column PHAS contains the unadjusted values of PHAS, CTIFILE = “NONE,” and CTLCORR = F”.

1.4 Processing

The tool should produce a warning if TIMEDEL is not in the range specified by the corresponding calibration-boundary (“CBD”) keyword.

If `apply_cti = "yes,"` the column PHAS_ADJ is created and populated with the values of the CTI-adjusted contents of PHAS. The column PHAS contains the unadjusted PHAS information. The original PHAS information is retained to ensure that users can analyze the unadjusted distribution of charge in the event island and to provide the input required if users want to rerun `acis_process_events` with an updated CTI ARD file at a later time. The algorithm used to compute the CTI-adjusted values of PHAS_ADJ is described later in this section. After the values of PHAS_ADJ are computed, the values of FLTGRADE, GRADE, PHA, ENERGY, and PI are computed from the column PHAS_ADJ not PHAS (see Tables 1 and 2). The column PHA has integer values whether the CTI-adjustment is applied or not.

The columns PHAS_ADJ and PHAS are arrays. For TIMED FAINT-mode observations, the relative CHIPX and CHIPY coordinates associated with $\text{PHAS_ADJ}[i, j]$ are distributed as shown in figure 1 with i and $j \in [1, 3]$. If a TIMED FAINT-mode event occurs at $(\text{CHIPX}, \text{CHIPY}) = (960, 571)$, then $\text{PHAS_ADJ}[1, 2]$ corresponds to the CCD coordinates (959,571) and $\text{PHAS_ADJ}[2, 3]$ corresponds to the CCD coordinates (960,572). The algorithm described below applies only to a 3 pixel \times 3 pixel event island. For TIMED VFaint-mode observations, i and $j \in [1, 5]$ and the appropriate 3 pixel \times 3 pixel region to use is the central nine pixels of the 5 pixel \times 5 pixel event island (i.e. the region associated with $\text{PHAS}[i, j]$, where i and $j \in [2, 4]$ instead of i and $j \in [1, 5]$). The outer sixteen pixels of the 5 \times 5 island are not modified by the CTI-adjustment algorithm. These sixteen pixels have identically the same values in the columns PHAS_ADJ and PHAS.

If `apply_cti = "yes,"` the following steps describe how to apply the CTI adjustment. The adjustment is applied to every event in the input ACIS event-data file. For an event detected on $\text{CCD_ID} = n$ at a location $\text{CHIPX} = x_{\text{CCD}}$, and $\text{CHIPY} = y_{\text{CCD}}$,

1. Copy the contents of PHAS to PHAS_ADJ.
2. Copy the values of PHAS_ADJ (not PHAS) to PHAS_TMP.
3. For the bottom row of the 3 \times 3 pixel event island, compute the effects of parallel CTI. Steps 3–5 should be performed only if the appropriate parallel-CTI trap-density map exists for $\text{CCD_ID} = n$. The CTI ARD may not contain some parallel-CTI trap-density maps if the effects of parallel CTI

are not fully calibrated. The bottom row of PHAS $[i, j]$ is given by $i \in [1, 3], j = 1$ (fig. 1). If PHAS_ADJ $[i, 1] \geq$ the split threshold, then

$$\begin{aligned} \text{DIFF_Y}[i, 1] &= \text{DELTPHAY}_{i,1} + \\ &\text{PHAS}[i, 1] - \text{PHAS_ADJ}[i, 1]. \end{aligned} \quad (1)$$

The quantity DIFF_Y $[i, j]$ is an estimate of the amount of charge that should be added to pixel $[i, j]$ of the event island. The quantity DELTPHAY $_{i,j}$ represents the amount of charge lost from pixel $[i, j]$ due to parallel CTI and is a function of the CCD used, the location of an event on the CCD, and the charge deposited on the CCD.

The value of DELTPHAY $_{i,j}$ used in equation 1 is computed as follows.

- i. Find the row m in HDU 1 of the appropriate CTI ARD file that satisfies the conditions

$$\text{CCD_ID}_m = n, \quad (2)$$

$$\text{CHIPXMIN}_m \leq x_{\text{CCD}} \leq \text{CHIPXMAX}_m, \text{ and} \quad (3)$$

$$\text{CHIPYMIN}_m \leq y_{\text{CCD}} \leq \text{CHIPYMAX}_m, \quad (4)$$

where CCD_ID, CHIPXMIN, CHIPXMAX, CHIPYMIN, and CHIPYMAX are the names of columns in the CTI ARD file (see sec. 2).

- ii. For the row that satisfies these conditions, find the two non-zero (real!) values PHA $_k$ and PHA $_{k+1}$ such that

$$0 < \text{PHA}_k \leq \text{PHAS_ADJ}[i, j] < \text{PHA}_{k+1}, \quad (5)$$

where PHA $_k$ and PHA $_{k+1}$ are elements of the column PHA in the CTI ARD file.

- iii. Compute the effective ‘‘VOLUME’’ occupied by the charge in pixel $[i, j]$ using the linear interpolation

$$\begin{aligned} \text{VOLUME}_{i,j} &= \frac{\text{PHAS_ADJ}[i, j] - \text{PHA}_k}{\text{PHA}_{k+1} - \text{PHA}_k} \times (\text{VOLUME_Y}_{k+1} - \text{VOLUME_Y}_k) + \\ &\text{VOLUME_Y}_k, \end{aligned} \quad (6)$$

where VOLUME_Y $_k$ and VOLUME_Y $_{k+1}$ are the k^{th} and $(k+1)^{\text{th}}$ elements of the column VOLUME_Y in the CTI ARD file (see sec. 2). This formula is valid if and only if $1 \leq k < \text{NPOINTS}$ (i.e. if $\text{PHA}_1 \leq \text{PHAS_ADJ}[i, j] < \text{PHA}_{\text{NPOINTS}}$, where PHA $_1$ and PHA $_{\text{NPOINTS}}$ are the smallest and largest values of the vector PHA for row m , respectively). If $0 < \text{PHAS_ADJ}[i, j] < \text{PHA}_1$, then use the linear extrapolation

$$\begin{aligned} \text{VOLUME}_{i,j} &= \frac{\text{PHAS_ADJ}[i, j] - \text{PHA}_1}{\text{PHA}_2 - \text{PHA}_1} \times (\text{VOLUME_Y}_2 - \text{VOLUME_Y}_1) + \\ &\text{VOLUME_Y}_1. \end{aligned} \quad (7)$$

If PHAS_ADJ $[i, j] \geq \text{PHA}_{\text{NPOINTS}}$, then use the linear extrapolation

$$\begin{aligned} \text{VOLUME}_{i,j} &= \frac{\text{PHAS_ADJ}[i, j] - \text{PHA}_{\text{NPOINTS}-1}}{\text{PHA}_{\text{NPOINTS}} - \text{PHA}_{\text{NPOINTS}-1}} \times \\ &(\text{VOLUME_Y}_{\text{NPOINTS}} - \text{VOLUME_Y}_{\text{NPOINTS}-1}) + \\ &\text{VOLUME_Y}_{\text{NPOINTS}-1}. \end{aligned} \quad (8)$$

If PHAS_ADJ $[i, j] \leq 0$, then VOLUME $_{i,j} = 0$.

- iv. Find the HDU in the CTI ARD file that has the parallel-CTI trap-density map for CCD_ID = n (see sec. 2). Set TRAPDENS $[i, j]$ equal to the value of the map at the position (CHIPX, CHIPY) = (x_i, y_i) , where $x_i = x_{\text{CCD}} - 1, x_{\text{CCD}}$, and $x_{\text{CCD}} + 1$ for $i = 1, 2$, and 3 and $y_i = y_{\text{CCD}} - 1, y_{\text{CCD}}$, and $y_{\text{CCD}} + 1$ for $j = 1, 2$, and 3 (for timed-exposure mode observations) or $y_i = \text{floor}(y_{\text{CCD}} - 0.5), \text{floor}(y_{\text{CCD}} + 0.5),$ and $\text{floor}(y_{\text{CCD}} + 1.5)$ for $j = 1, 2$, and 3 (for continuous-clocking mode observations). Also note that in continuous-clocking mode observations, y_{CCD} is the CHIPY value of the target location instead of the read-out value of CHIPY.

v. Compute the value of $\text{DELTPHAY}_{i,j}$:

$$\text{DELTPHAY}_{i,j} = \text{TRAPDENS}_{i,j} \times \text{VOLUME}_{i,j}. \quad (9)$$

4. For the middle and top rows of the 3×3 pixel event island, compute the effects of parallel CTI. The middle and top rows of $\text{PHAS}[i, j]$ are given by $i \in [1, 3]$, $j \in [2, 3]$ (fig. 1). If $\text{PHAS_ADJ}[i, j] \geq$ the split threshold $> \text{PHAS_ADJ}[i, j - 1]$, then

$$\begin{aligned} \text{DIFF_Y}[i, j] &= \text{DELTPHAY}_{i,j} + \\ &\quad \text{PHAS}[i, j] - \text{PHAS_ADJ}[i, j]. \end{aligned} \quad (10)$$

If $\text{PHAS_ADJ}[i, j] \geq \text{PHAS_ADJ}[i, j - 1] \geq$ the split threshold, then

$$\begin{aligned} \text{DIFF_Y}[i, j] &= (\text{DELTPHAY}_{i,j} - \text{DELTPHAY}_{i,j-1}) + \\ &\quad \text{PHAS}[i, j] - \text{PHAS_ADJ}[i, j]. \end{aligned} \quad (11)$$

If $\text{PHAS_ADJ}[i, j - 1] > \text{PHAS_ADJ}[i, j] \geq$ the split threshold, then

$$\begin{aligned} \text{DIFF_Y}[i, j] &= \text{FRCTRLY}n \times (\text{DELTPHAY}_{i,j} - \text{DELTPHAY}_{i,j-1}) + \\ &\quad \text{PHAS}[i, j] - \text{PHAS_ADJ}[i, j], \end{aligned} \quad (12)$$

where $\text{FRCTRLY}n$ is the name of a keyword in the CTI ARD file (see sec. 2) and represents the fraction of the trapped charge that is released in the first pixel following the pixel which lost the charge.

5. Use the estimate of the effects of parallel CTI to adjust the 3×3 pixel event island PHAS_ADJ . For i and $j \in [1, 3]$,

$$\text{PHAS_ADJ}[i, j] = \text{PHAS_ADJ}[i, j] + \text{DIFF_Y}[i, j]. \quad (13)$$

Pixels whose amount of charge $<$ the split threshold are not modified. These pixels have the same values in the columns PHAS and PHAS_ADJ .

6. For the column of a 3×3 pixel event island that is closest to the serial read-out node, compute the effects of serial CTI. Steps 6–8 should be performed only if the appropriate serial-CTI trap-density map exists for $\text{CCD_ID} = n$. The CTI ARD may not contain some serial-CTI trap-density maps if the effects of serial CTI are not fully calibrated.

- i. For $\text{NODE_ID} = 0$, $i = 1$ and $j \in [1, 3]$. If $\text{PHAS_ADJ}[1, j] \geq$ the split threshold, then

$$\begin{aligned} \text{DIFF_X}[1, j] &= \text{DELTPHAX}_{1,j} + \\ &\quad \text{PHAS}[1, j] - \text{PHAS_ADJ}[1, j]. \end{aligned} \quad (14)$$

- ii. For $\text{NODE_ID} = 1$, $i = 3$ and $j \in [1, 3]$. If $\text{PHAS_ADJ}[3, j] \geq$ the split threshold, then

$$\begin{aligned} \text{DIFF_X}[3, j] &= \text{DELTPHAX}_{3,j} + \\ &\quad \text{PHAS}[3, j] - \text{PHAS_ADJ}[3, j]. \end{aligned} \quad (15)$$

- iii. For $\text{NODE_ID} = 2$, $i = 1$ and $j \in [1, 3]$. If $\text{PHAS_ADJ}[1, j] \geq$ the split threshold, then

$$\begin{aligned} \text{DIFF_X}[1, j] &= \text{DELTPHAX}_{1,j} + \\ &\quad \text{PHAS}[1, j] - \text{PHAS_ADJ}[1, j]. \end{aligned} \quad (16)$$

- iv. For $\text{NODE_ID} = 3$, $i = 3$ and $j \in [1, 3]$. If $\text{PHAS_ADJ}[3, j] \geq$ the split threshold, then

$$\begin{aligned} \text{DIFF_X}[3, j] &= \text{DELTPHAX}_{3,j} + \\ &\quad \text{PHAS}[3, j] - \text{PHAS_ADJ}[3, j]. \end{aligned} \quad (17)$$

The quantity $\text{DIFF_X}[i, j]$ is an estimate of the amount of charge that should be added to pixel $[i, j]$. The quantity $\text{DELTPHAX}_{i,j}$ represents the amount of charge lost from pixel $[i, j]$ due to the effects of serial CTI and is a function of the CCD used, the location of an event on the CCD, and the charge deposited on the CCD. This quantity is computed using the same linear interpolation (and extrapolation) method used to compute $\text{DELTPHAY}_{i,j}$, where VOLUME_Y is replaced with VOLUME_X and the parallel-CTI trap-density map for $\text{CCD_ID} = n$ is replaced with the serial-CTI trap-density map for the CCD.

7. For the two columns of a 3×3 pixel event island that are farthest from the serial read-out node, compute the effects of serial CTI.

- i. For $\text{NODE_ID} = 0$, $i \in [2, 3]$ and $j \in [1, 3]$. If $\text{PHAS_ADJ}[i, j] \geq \text{PHAS_ADJ}[i - 1, j] \geq$ the split threshold, then

$$\begin{aligned} \text{DIFF_X}[i, j] &= (\text{DELTPHAX}_{i,j} - \text{DELTPHAX}_{i-1,j}) + \\ &\quad \text{PHAS}[i, j] - \text{PHAS_ADJ}[i, j]. \end{aligned} \quad (18)$$

If $\text{PHAS_ADJ}[i, j] \geq$ the split threshold and $\text{PHAS_ADJ}[i, j] < \text{PHAS_ADJ}[i - 1, j]$, then

$$\begin{aligned} \text{DIFF_X}[i, j] &= \text{FRCTRLX}n \times (\text{DELTPHAX}_{i,j} - \text{DELTPHAX}_{i-1,j}) + \\ &\quad \text{PHAS}[i, j] - \text{PHAS_ADJ}[i, j]. \end{aligned} \quad (19)$$

- ii. For $\text{NODE_ID} = 1$, $i \in [1, 2]$ and $j \in [1, 3]$. If $\text{PHAS_ADJ}[i, j] \geq \text{PHAS_ADJ}[i + 1, j] \geq$ the split threshold, then

$$\begin{aligned} \text{DIFF_X}[i, j] &= (\text{DELTPHAX}_{i,j} - \text{DELTPHAX}_{i+1,j}) + \\ &\quad \text{PHAS}[i, j] - \text{PHAS_ADJ}[i, j]. \end{aligned} \quad (20)$$

If $\text{PHAS_ADJ}[i, j] \geq$ the split threshold and $\text{PHAS_ADJ}[i, j] < \text{PHAS_ADJ}[i + 1, j]$, then

$$\begin{aligned} \text{DIFF_X}[i, j] &= \text{FRCTRLX}n \times (\text{DELTPHAX}_{i,j} - \text{DELTPHAX}_{i+1,j}) + \\ &\quad \text{PHAS}[i, j] - \text{PHAS_ADJ}[i, j]. \end{aligned} \quad (21)$$

- iii. For $\text{NODE_ID} = 2$, $i \in [2, 3]$ and $j \in [1, 3]$. If $\text{PHAS_ADJ}[i, j] \geq \text{PHAS_ADJ}[i - 1, j] \geq$ the split threshold, then

$$\begin{aligned} \text{DIFF_X}[i, j] &= (\text{DELTPHAX}_{i,j} - \text{DELTPHAX}_{i-1,j}) + \\ &\quad \text{PHAS}[i, j] - \text{PHAS_ADJ}[i, j]. \end{aligned} \quad (22)$$

If $\text{PHAS_ADJ}[i, j] \geq$ the split threshold and $\text{PHAS_ADJ}[i, j] < \text{PHAS_ADJ}[i - 1, j]$, then

$$\begin{aligned} \text{DIFF_X}[i, j] &= \text{FRCTRLX}n \times (\text{DELTPHAX}_{i,j} - \text{DELTPHAX}_{i-1,j}) + \\ &\quad \text{PHAS}[i, j] - \text{PHAS_ADJ}[i, j]. \end{aligned} \quad (23)$$

- iv. For $\text{NODE_ID} = 3$, $i \in [1, 2]$ and $j \in [1, 3]$. If $\text{PHAS_ADJ}[i, j] \geq \text{PHAS_ADJ}[i + 1, j] \geq$ the split threshold, then

$$\begin{aligned} \text{DIFF_X}[i, j] &= (\text{DELTPHAX}_{i,j} - \text{DELTPHAX}_{i+1,j}) + \\ &\quad \text{PHAS}[i, j] - \text{PHAS_ADJ}[i, j]. \end{aligned} \quad (24)$$

If $\text{PHAS_ADJ}[i, j] \geq$ the split threshold and $\text{PHAS_ADJ}[i, j] < \text{PHAS_ADJ}[i + 1, j]$, then

$$\begin{aligned} \text{DIFF_X}[i, j] &= \text{FRCTRLX}n \times (\text{DELTPHAX}_{i,j} - \text{DELTPHAX}_{i+1,j}) + \\ &\quad \text{PHAS}[i, j] - \text{PHAS_ADJ}[i, j], \end{aligned} \quad (25)$$

where $\text{FRCTRLX}n$ is the name of a keyword in the CTI ARD file (see sec. 2) and represents the fraction of the trapped charge that is released in the first pixel following the pixel which lost the charge.

Table 1. Input Conditions

Case	Parameter apply_cti ^a	Parameter doevtgrade	Parameter calculate_pi	Keyword CTI_CORR
1 ^b	yes	yes	yes	F
2	yes	yes	yes	T
3	yes	yes	no	F
4	yes	yes	no	T
5	yes	no	yes	F
6	yes	no	yes	T
7	yes	no	no	F
8	yes	no	no	T
9	no	yes	yes	F
10	no	yes	yes	T
11	no	yes	no	F
12	no	yes	no	T
13	no	no	yes	F
14	no	no	yes	T
15	no	no	no	F
16	no	no	no	T

^a If DATAMODE = GRADED, GRADED_HISTO, CC_GRADED, or CC33_GRADED, then follow the instructions for apply_cti=no because it is not possible to perform a CTI adjustment.

^b This case is appropriate for standard pipeline processing.

8. Use the estimate of the effects of serial CTI to adjust the 3×3 pixel event island PHAS_ADJ. For i and $j \in [1, 3]$,

$$\text{PHAS_ADJ}[i, j] = \text{PHAS_ADJ}[i, j] + \text{DIFF_X}[i, j]. \quad (26)$$

Pixels whose amount of charge < the split threshold are not modified. These pixels have the same values in the columns PHAS and PHAS_ADJ.

9. Repeat steps 2–8 until the absolute values of $\text{PHAS_ADJ}[i, j] - \text{PHAS_TMP}[i, j]$ are less than the value of the parameter `cti_converge` for all pixels in the 3×3 pixel event island (i.e. until the changes in each of the values of $\text{PHAS_ADJ}[i, j]$ from one iteration to the next are less than the value of the parameter `cti_converge`). The maximum number of times that steps 2–8 should be performed is specified by the parameter `max_cti_iter`. If the CTI-adjustment process does not converge after `max_cti_iter` iterations, set the values of PHAS_ADJ to be the values obtained during the last iteration and set STATUS bit 20 (of bits 0–31) equal to one.
10. Based on the input conditions shown in Table 1, compute the values of PHA, ENERGY, PI, FLT-GRADE, GRADE, etc. as shown in Table 2.
11. Write out the results.

2 New CTI ARD

Since the effects of CTI are temperature dependent, a different CTI ARD file is required for each of the different focal-plane temperatures. The CTI ARD files have the following structure.

2.1 HDU 1 Keywords

- FRCTRLX_{*n*}

Table 2. Output^a

Case	Column PHA ^b	Column ENERGY	Column PI	Column FLTGRADE ^b	Column GRADE	STATUS bit 20 ^c	Keyword CTI_CORR	Keyword CTIFILE	Keyword GAINFILE
1 ^d	C ^e	C	C	C	C	set	T	<cti> ^f	<gain_cti> ^g
2	C	C	C	C	C	set	T	<cti>	<gain_cti>
3	C	DNC ^h	DNC	C	C	set	T	<cti>	copy
4	C	DNC	DNC	C	C	set	T	<cti>	copy
5	DNC	C	C	DNC	DNC	unset	F	“NONE”	<gain> ⁱ
6	DNC	C	C	DNC	DNC	copy	T	copy	<gain_cti>
7	DNC	DNC	DNC	DNC	DNC	unset	F	“NONE”	copy
8	DNC	DNC	DNC	DNC	DNC	copy	T	copy	copy
9	C	C	C	C	C	unset	F	“NONE”	<gain>
10 ^j	C	C	C	C	C	unset	F	“NONE”	<gain>
11	C	DNC	DNC	C	C	unset	F	“NONE”	copy
12	C	DNC	DNC	C	C	unset	F	“NONE”	copy
13	DNC	C	C	DNC	DNC	unset	F	“NONE”	<gain>
14	DNC	C	C	DNC	DNC	copy	T	copy	<gain_cti>
15	DNC	DNC	DNC	DNC	DNC	unset	F	“NONE”	copy
16	DNC	DNC	DNC	DNC	DNC	copy	T	copy	copy

^a In all cases, the PHAS values in the output file are the unadjusted values of the pulse heights in the 3 pixel \times 3 pixel (or 5 pixel \times 5 pixel) event islands. The values of PHAS_ADJ are only (re)computed if apply_cti=yes.

^b If apply_cti=yes, then the values of PHAS_ADJ are used to compute the values of PHA and FLTGRADE. If apply_cti=no, then the values of PHAS are used to compute the values of PHA and FLTGRADE. The values of PHA are integers in both cases.

^c If apply_cti=yes, then STATUS bit 20 (of 0–31) is set to one for an event only if the PHAS adjustments for the event have not converged after performing the specified maximum number of trials. STATUS bit 20 should be (re)set to zero first before performing the CTI adjustment.

^d This case is used for standard pipeline processing.

^e (Re)computed.

^f The name of the CTI ARD file used to perform the CTI adjustments.

^g The name of the gain ARD file used to compute ENERGY from PHA. This file is appropriate for CTI-adjusted data.

^h Copied, not (re)computed.

ⁱ The name of the gain ARD file used to compute ENERGY from PHA. This file is appropriate for data that has not had the CTI adjustment applied.

^j The effects of the CTI adjustment are removed.

- FRCTRLX_n

The keywords FRCTRLX_n and FRCTRLY_n represent the fraction of the trapped charge that is released in the first pixel following the pixel which lost the charge.

2.2 HDU 1 Columns

- CCD_ID
- CHIPXMIN
- CHIPXMAX
- CHIPYMIN
- CHIPYMAX
- NPOINTS
- PHA (a vector with NPOINTS elements)

Figure 1: The relative CHIPX and CHIPY coordinates of the nine elements of a 3×3 ACIS event island (i.e. the nine elements of PHAS and PHAS_ADJ for TIMED FAINT-mode events).

- VOLUME_X (a vector with NPOINTS elements)
- VOLUME_Y (a vector with NPOINTS elements)

The columns CCD_ID, CHIPXMIN, CHIPXMAX, CHIPYMIN, and CHIPYMAX are used to define a complete set of spatially-separate regions on the ACIS CCDs. The pulse-height-dependent effects of parallel CTI are tabulated for each region in the columns PHA and VOLUME_Y. The column VOLUME_X is a place-holder in case the effects of serial CTI are calibrated. It is unused at the present. Each row of HDU 1 corresponds to one region of an ACIS CCD and has NPOINTS PHA, VOLUME_X, and VOLUME_Y elements.

2.3 HDUs ≥ 2

Each one of these extensions (up to a maximum of twenty) contains either a parallel or serial trap-density map for one of the ten ACIS CCDs. (Only parallel maps exist at the present). These maps are recorded separately for each CCD. The trap density of each of the 1024×1024 pixels in a parallel CTI map is the mean trap density for the pixel multiplied by the CHIPY coordinate of the pixel (i.e. the integrated trap density along the column associated with the pixel). The trap densities are stored as two-byte integers with appropriate keywords BZERO and BSCALE in the headers of each extension. (The trap density = BZERO + BSCALE \times the value of the trap density in the image.) The use of two-byte integers instead of four-byte real numbers helps reduce the size of the ARD file.

2.4 Size of File

The CTI ARD files are relatively large. Each row of HDU 1 has six two-byte integers and three four-byte real vectors with NPOINTS elements each. If the CTI ARD contains information for one region (the entire CCD) on each of the ten ACIS CCDs and if NPOINTS = 100, the binary table of HDU 1 comprises $10 \times 1 \times (6 \times 2 + 3 \times 4 \times 100)$ bytes = 12.1 kb of information. The size of each of the twenty trap-density maps is 2.1 Mb (i.e. 1024×1024 pixels \times 2 bytes/pixel). Unless the number of regions per CCD becomes much larger than one, the size of HDU 1 is much smaller than the size of the trap-density maps and the size of one CTI ARD file can be as large as 42 Mb (i.e. 20 hdus \times 2.1 Mb/hdu).
